

Thermal Effective Potential of the $O(N)$ Linear σ Model

Giovanni AMELINO-CAMELIA

Theoretical Physics, University of Oxford, 1 Keble Rd., Oxford OX1 3NP, UK

ABSTRACT

The finite-temperature effective potential of the $O(N)$ linear σ model is studied, with emphasis on the implications for the investigation of hot hadron dynamics. The contributions from all the “bubble diagrams” are fully taken into account for arbitrary N ; this also allows to address some long-standing issues concerning the use of non-perturbative approaches in (finite-temperature) field theory.

arXiv:hep-ph/9702403v1 23 Feb 1997

The temperature-induced phase transition of the $O(N)$ Linear σ Model ($L\sigma M$) has recently attracted renewed interest, especially as a model of the chiral phase transition that might be triggered by certain ultrarelativistic collisions of hadrons or nuclei. While some of the relevant experimental signatures, such as the ones associated to *disoriented chiral condensates* (see, *e.g.*, Refs. [1-3]), are best estimated within the framework of non-equilibrium (classical or quantum) field theory [3-8], there is also considerable interest (see, *e.g.*, the recent Refs. [9-11]) in the quasi-equilibrium/thermal description of the chiral phase transition. Moreover, some of the scenarios of phenomenological interest consist [5, 6] of a first stage in which thermal equilibrium is reached, followed by a stage in which the system evolves out of equilibrium. The present note is devoted to the study of the “thermal” (finite-temperature) effective potential of the $O(N)$ $L\sigma M$, which is an essential theoretical tool for the analysis of quasi-equilibrium/thermal properties.

The difficulties involved in the evaluation of thermal effective potentials have been confronting the physics community for decades. They were first encountered in the study of certain condensed-matter problems, but even for what concerns those problems a general consensus on the procedures to be followed has not yet been reached (see the recent Ref. [10] and references therein). In the context of the relativistic quantum field theories of interest to particle physics the same, essentially infrared, problems associated to the description of thermal effects are accompanied by the familiar “pathology” of ultraviolet divergencies. The need to resort to non-perturbative approaches in the analysis of thermal effective potentials was already emphasized to the particle-physics community more than 20 years ago, in the works [12] that provided technical support for the Kirzhnits-Linde [13] proposal of “symmetry restoration” (thermal field fluctuations at sufficiently high temperatures restore symmetries broken *a la* Higgs in vacuum). In particular, it was immediately clear that at high temperatures the “bubble diagrams” [12, 14, 15] (see, Fig. 1) of any order in the coupling constants could not be neglected in any consistent approximation, even if the coupling constants are small, as a result of the fact that “bubble subgraphs” contribute a factor proportional to the square of the temperature. This has motivated the development of various approaches to the resummation of such bubble diagrams. [In the case of the $O(N)$ $L\sigma M$ as a model of hadron dynamics the coupling constant is itself large, and even at small temperatures it is necessary to study the non-perturbative sector.]

In the study of relativistic field theories with N scalar fields, the proposed approaches to bubble-resummation can be divided in two broad categories; attempts aiming at the exact resummation of all bubble diagrams, sometimes referred to as Hartree approaches, and attempts aiming at the resummation of only those bubble diagrams that would *survive* the $N \rightarrow \infty$ limit, usually referred to as large- N approaches¹. After 20 years of debate only rather recently some consensus has emerged on the Hartree side; in fact, the independent studies [16, 17] have compared various Hartree approaches² proposed for the study of thermal effective potentials, and found that only the one proposed in Ref.[20] by Pi and this author (which was based on the CJT formalism [21]) and the one proposed in Ref. [22] by Kirzhnits and Linde lead to reliable results. Much less controversy has affected large- N analyses of the thermal effective potential (see, *e.g.*, Refs. [12, 23]); in fact, the large- N limit significantly simplifies the counting of multiloop bubble diagrams, which is the most common source of inaccuracy.

¹The conventional large- N approach for theories in vacuum (at zero temperature) also involves some non-bubble (“sunset-type”) contributions; however, at high temperatures, in light of the above-mentioned fact that the bubble diagrams are dominant, it makes sense to limit the large- N approach to bubble diagrams. It is this truncated version that is qualified as large- N approach in the present note.

²The studies [16, 17] focused on diagrammatic techniques useful in the analysis of scalar theories. A technique based on the analysis of “hard thermal loops” [18] can also be very useful in the study of thermal effective potentials, but its natural framework is the one of gauge theories. Moreover, it is well known that the Hartree approach can be implemented in a non-diagrammatic way, through the use of gaussian wave functionals [19].

Figure 1: As examples of “bubble diagrams”, the “2-bubble diagram” is drawn in (1.a) and one of the “8-bubble diagrams” is drawn in (1.b).

In modeling (part of) the hadron dynamics associated to ultrarelativistic collisions of hadrons or nuclei the $O(4)$ $L\sigma M$ appears to be most relevant [3], and the large- N approach might be too drastic when $N = 4$. Unfortunately, the historically poor understanding (reviewed in the recent Ref. [11]) of the ultraviolet structures encountered when performing the complete resummation of bubble diagrams with $N > 1$ has been obstructing the way of analyses within the Hartree thermal effective potential. It is perhaps because of these problems that even recent studies of the $O(4)$ $L\sigma M$ at finite temperature have chosen to dispose of ultraviolet divergences in one or another *ad hoc* (unjustified) fashion (see, *e.g.* Ref. [11]) or drop quantum effects altogether (see, *e.g.* Ref. [9]). However, the “ultraviolet problems” of the Hartree approach are to be ascribed to poor handling of the difficult formalism, rather than being inherent; in fact, this author’s recent investigation of the ultraviolet structure of the Hartree (thermal) effective potential in a theory with two scalar fields [24] has shown that this potential is indeed renormalizable when the contributions from all the bubble diagrams are included (with correct counting and symmetry factors) and the interdependence of the gap equations for the dressed propagators is properly taken into account.

In the present note the formalism developed in [20, 21, 24] is used to obtain the Hartree bubble-resummed thermal effective potential of the $O(N)$ $L\sigma M$ for arbitrary N , and in particular the ultraviolet sector is found to be renormalizable. Besides providing a useful tool for future investigations of the $L\sigma M$ at finite temperature, this result also allows to investigate some of the differences between the Hartree and the large- N approach (of course, the exact resummation of all bubble diagrams performed in the following for arbitrary N also entails, upon appropriate limiting procedure, the corresponding large- N approximation). In particular, it is emphasized below that, although both approaches are renormalizable, when considered as effective low-energy descriptions, with finite cut-off, they manifest a rather different dependence on the cut-off. Also prominent among the issues debated in relation to the differences between Hartree and large- N is Goldstone’s theorem, which is generally expected to be verified in the large- N approach, but violated in the Hartree approach. However, this expectation emerged from analyses of unrenormalized Hartree equations (see, *e.g.* [5, 6]), and it is emphasized below that renormalization can modify substantially the structures relevant for Goldstone’s theorem.

Having set the agenda for the present note, let us start its computational part by writing explicitly the Lagrangian density of the $O(N)$ $L\sigma M$

$$L = -\frac{1}{2}(\partial_\mu \sigma)(\partial^\mu \sigma) - \frac{1}{2}(\partial_\mu \vec{\pi})(\partial^\mu \vec{\pi}) - \frac{m^2}{2}(\sigma^2 + \vec{\pi}^2) - \frac{\lambda}{6N}(\sigma^2 + \vec{\pi}^2)^2, \quad (1)$$

where the pion vector field is understood to have $N-1$ components.

As clarified in Refs. [11, 16, 17, 20, 24, 25], the most convenient method of evaluation of the thermal effective potential including the contribution from the complete (Hartree)

sum of bubble diagrams emerges within the CJT formalism[21, 26, 27] and involves the bubble-resummed (dressed) propagator $D_{\text{O}}(\phi; k)$:

$$V_{\text{O}}(\phi) = W_{\text{O}}[\phi; D_{\text{O}}(\phi; k)] \equiv V_{\text{tree}} - \frac{1}{2} \oint_k \ln D_{\text{O}} + \frac{1}{2} \oint_k [D_{\text{tree}}^{-1} D_{\text{O}} - 1] + W^*[\phi; D_{\text{O}}] , \quad (2)$$

where ϕ , the “classical field”, is the usual c-number argument of the effective potential, V_{tree} and D_{tree} are the tree-level potential and propagator respectively, and W^* includes all the “2-bubble diagrams” (*i.e.* diagrams with the topology of two rings touching at one point as in Fig. 1.a) with lines representing $D_{\text{O}}(\phi; k)$. The bubble-resummed propagator $D_{\text{O}}(\phi; k)$ can be obtained [21] as the function that stationarizes $W_{\text{O}}[\phi; D]$ with respect to D -variations. Also notice that the conventional *sum-integral* notation is used in (2) to denote the combination of integration over spatial components of the momentum and sum over Matsubara frequencies characteristic of finite-temperature field theory in the imaginary time formalism.

In the case of the $O(N)$ L σ M one is interested in the effective potential V as a function of the classical field associated to the shift $\{\sigma, \vec{\pi}\} \rightarrow \{\sigma + N^{1/2}\phi, \vec{\pi}\}$; in fact, in physical applications the potential is tilted in the σ direction by a chiral symmetry-breaking term, which is ignored here for simplicity. (The factor $N^{1/2}$ is convenient, since it renders [28] the symmetry-breaking value of ϕ essentially independent of N .) The Hartree bubble-resummed effective potential corresponding to this σ shift can be written as

$$\begin{aligned} V_{\text{O}} = & \frac{Nm^2}{2}\phi^2 + \frac{N\lambda}{6}\phi^4 + \frac{1}{2} \oint_k \{ \ln[k^2 + M_{\sigma}^2] + (N-1) \ln[k^2 + M_{\pi}^2] \} \\ & - \frac{1}{2} [M_{\sigma}^2 - m^2 - 2\lambda\phi^2] P[M_{\sigma}] - \frac{N-1}{2} [M_{\pi}^2 - m^2 - \frac{2\lambda}{3}\phi^2] P[M_{\pi}] \\ & + \frac{\lambda}{2N} (P[M_{\sigma}])^2 + \frac{\lambda}{6} \frac{N^2 - 1}{N} (P[M_{\pi}])^2 + \frac{\lambda}{3} \frac{N-1}{N} P[M_{\pi}] P[M_{\sigma}] , \end{aligned} \quad (3)$$

where for convenience V_{O} has been expressed (without loss of generality) in terms of the dressed masses M_{σ} and M_{π} rather than the dressed propagator D_{O} . The relation between M_{σ} , M_{π} and D_{O} is $[D_{\text{O}}^{-1}]_{\Psi, \chi} \equiv \delta_{\Psi\sigma} \delta_{\chi\sigma} (k^2 + M_{\sigma}) + \delta_{\Psi\pi} \delta_{\chi\pi} (k^2 + M_{\pi})$, and from the above-mentioned stationarization requirement for the dressed propagators one obtains in the case of the $O(N)$ L σ M the following “gap equations” for the dressed masses³

$$M_{\sigma}^2 = m^2 + 2\lambda\phi^2 + \frac{2\lambda}{N} P[M_{\sigma}] + \frac{2\lambda}{3} \frac{N-1}{N} P[M_{\pi}] , \quad (4)$$

$$M_{\pi}^2 = m^2 + \frac{2\lambda}{3}\phi^2 + \frac{2\lambda}{3} \frac{N+1}{N} P[M_{\pi}] + \frac{2\lambda}{3N} P[M_{\sigma}] . \quad (5)$$

Here and in (3), $P[M]$ denotes the “tadpole” [12, 15]

$$P[M] \equiv \oint_p [p^2 + M^2(\phi; p)]^{-1} = I_1 - M^2 I_2 + P_f[M] \quad (6)$$

$$P_f[M] \equiv \frac{M^2}{16\pi^2} \ln \frac{M^2}{\mu^2} - \int \frac{d^3 k}{(2\pi)^3} \left[\sqrt{|\mathbf{k}|^2 + M^2} \left(1 - \exp \left(\frac{\sqrt{|\mathbf{k}|^2 + M^2}}{T} \right) \right) \right]^{-1} , \quad (7)$$

³While stopping short of investigating the Hartree thermal effective potential, the recent work [11] did report candidate gap equations for the dressed masses in the case $N=4$. Those gap equations are however incorrect, as the reader can easily see by comparison with (4). As in other instances in the related literature, the inaccuracies in the gap equations of Ref. [11] can be associated to the handling of the pion degrees of freedom as if they were not independent. Of course they are independent, but ultimately the symmetries provide the pions with a common dressed mass M_{π} .

where μ is an arbitrary (renormalization) scale, and I_1 and I_2 have been separated out as contributions that diverge in the limit of infinite ultraviolet momentum cut-off Λ

$$I_1 = \Lambda^2/(8\pi^2) , \quad I_2 = (\ln \Lambda^2/\mu^2)/(16\pi^2) . \quad (8)$$

The conventional argument concerning violations of Goldstone's theorem in Hartree is reflected within this formalism in the fact that M_π does not vanish at a symmetry-breaking ($\phi \neq 0$) minimum of the potential, as *formally* encoded in the (unrenormalized) relation

$$\frac{dV_\square}{d\phi} = \frac{\partial V_\square}{\partial \phi} + \frac{\partial V_\square}{\partial M} \frac{\partial M}{\partial \phi} = \frac{\partial V_\square}{\partial \phi} \propto \phi \left[M_\pi^2 + \frac{4}{3} \frac{\lambda}{N} (P[M_\sigma] - P[M_\pi]) \right] . \quad (9)$$

Instead, to the same level of analysis, one finds that Goldstone's theorem does hold in the large- N approach, as implied by the $N \rightarrow \infty$ limit of Eq. (9).

In proceeding toward the renormalization of the effective potential and gap equations it is important to realize that the divergences originate from the “tadpole” discussed above and the “one loop”

$$\oint_k \ln[k^2 + M^2] = -\frac{M^4}{4} I_2 + \frac{M^2}{2} I_1 + Q_f[M] \quad (10)$$

$$Q_f[M] \equiv \frac{M^4}{64\pi^2} \left[\ln \frac{M^2}{\mu^2} - \frac{1}{2} \right] + T \int \frac{d^3 k}{(2\pi)^3} \ln \left[1 - \exp \left(\frac{\sqrt{|\mathbf{k}|^2 + M^2}}{T} \right) \right] . \quad (11)$$

Renormalized (*i.e.* finite in the $\Lambda \rightarrow \infty$ limit) expressions are obtained upon introducing renormalized coupling and mass that are related to the bare ones by

$$\frac{m_R^2}{\lambda_R} = \frac{m^2}{\lambda} + \frac{2}{3} \frac{N+2}{N} I_1 , \quad \frac{1}{\lambda_R} = \frac{1}{\lambda} + \frac{2}{3} \frac{N+2}{N} I_2 . \quad (12)$$

It is important that, given a positive value of the renormalized coupling λ_R , the bare coupling is positive only for Λ smaller than the Λ_L corresponding to the Landau pole⁴. For $\Lambda > \Lambda_L$ the bare coupling is negative, and in particular $\lambda \rightarrow 0^-$ as $\Lambda \rightarrow \infty$. The renormalizability of the Hartree bubble-resummed finite-temperature effective potential and gap equations is manifest in the fact that, with some tedious algebra here spared to the reader, one can rewrite the Eqs. (3)-(5) as sums of terms that are proportional to the bare coupling (*i.e.* terms that vanish in the $\Lambda \rightarrow \infty$ limit) and terms that involve only renormalized quantities:

$$\begin{aligned} M_\sigma^2 = & m_R^2 + \frac{2\lambda_R}{3} \frac{N+2}{N^2} (N\phi^2 + P_f[M_\sigma]) + \frac{2\lambda_R}{3} \frac{N^2+N-2}{N^2} P_f[M_\pi] \\ & + \frac{2\lambda}{\lambda_R} \frac{N-1}{N^2} (M_\pi^2 - M_\sigma^2) + \frac{4\lambda}{3} \frac{N^2+N-2}{N^3} (N\phi^2 + P_f[M_\sigma] - P_f[M_\pi]) , \end{aligned} \quad (13)$$

$$\begin{aligned} M_\pi^2 = & m_R^2 + \frac{2\lambda_R}{3} \frac{N+2}{N^2} (N\phi^2 + P_f[M_\sigma]) + \frac{2\lambda_R}{3} \frac{N^2+N-2}{N^2} P_f[M_\pi] \\ & + \frac{2\lambda}{\lambda_R} \frac{1}{N^2} (M_\sigma^2 - M_\pi^2) - \frac{4\lambda}{3} \frac{N+2}{N^3} (N\phi^2 + P_f[M_\sigma] - P_f[M_\pi]) , \end{aligned} \quad (14)$$

⁴This behavior is related to the well-known “triviality” of the theory [29], *i.e.* $\lambda_R \rightarrow 0$ as $\Lambda \rightarrow \infty$ if one insisted on $\lambda > 0$.

and (ignoring an irrelevant ϕ -independent contribution)

$$\begin{aligned}
V_{\bigcirc} = & Q_f[M_\sigma] + (N-1)Q_f[M_\pi] + \frac{N}{2}\phi^2 M_\sigma^2 + \frac{3}{4}\frac{N}{N+2}\frac{m_R^2}{\lambda_R}[M_\sigma^2 + (N-1)M_\pi^2] \\
& - \frac{3}{8}\frac{N}{N+2}\frac{M_\sigma^4 + (N-1)M_\pi^4}{\lambda_R} + \frac{1}{4}\frac{N-1}{N}(M_\pi^2 - M_\sigma^2)(N\phi^2 + P_f[M_\sigma] - P_f[M_\pi]) \\
& + \frac{3}{8}\frac{N-1}{N+2}\frac{(M_\sigma^2 - M_\pi^2)^2}{\lambda_R} - \frac{N\lambda}{3}\phi^4. \tag{15}
\end{aligned}$$

If one was exclusively interested in a proof of the renormalizability of the Hartree bubble-resummed thermal⁵ effective potential the terms proportional to the bare coupling λ in the Eqs. (13)-(15) could have been simply dropped since they vanish in the infinite cut-off limit. However, in physical analyses of the $O(N)$ L σ M, besides the renormalizability of the approach, which provides an indication of overall consistency and is also important at the formal level, one is also interested in the structure of the theory with a finite cut-off. In fact, this is motivated mathematically by the implications of the above-mentioned Landau-pole structure (in the $\Lambda \rightarrow \infty$ limit the theory is unstable), and phenomenologically by the fact that the $O(N)$ L σ M is useful only as a low-energy effective description of hadron dynamics. With a finite cut-off (small enough to keep at a safe distance from the Landau pole [5, 6]) all the terms proportional to λ in the Eqs. (13)-(15) are to be taken into account and lead to the unwanted result that the Hartree thermal effective potential is rather sensitive to the value of the cut-off. It is worth emphasizing that, as manifest in the Eqs. (13)-(15), all the explicit dependence on the cut-off drops out in the large- N limit.

Let us now go back to the issues concerning Goldstone's theorem. It is important to notice that after renormalization Eq. (9) takes the form

$$\frac{dV_{\bigcirc}}{d\phi} \propto \phi \left[M_\pi^2 + \frac{8\lambda}{3}\frac{\phi^2}{N} + \frac{4\lambda}{3}\frac{N+2}{N^2}(P_f[M_\sigma] - P_f[M_\pi]) + \frac{\lambda}{\lambda_R}\frac{2}{N}(M_\pi^2 - M_\sigma^2) \right]. \tag{16}$$

Clearly, renormalization has changed things quite dramatically: in the $\Lambda \rightarrow \infty$ ($\lambda \rightarrow 0^-$) limit one finds from (16) that M_π vanishes at a symmetry-breaking ($\phi \neq 0$) minimum of the potential, as required by Goldstone's theorem. However, as clarified above, the behavior of the "renormalized" ($\Lambda \rightarrow \infty$) theory is not very relevant to phenomenological applications, and Eq. (16) does reflect a violation of Goldstone's theorem when the cut-off is finite. Therefore the generic expectation expressed in the literature, which relies on the analysis of unrenormalized relations, appears to hold in this weaker sense after renormalization is performed. Again, the large- N approach is better behaved, since the $N \rightarrow \infty$ limit of Eq. (16) is in agreement with Goldstone's theorem. It is this author's opinion that the analysis here reported suggests that the fundamental difference between the Hartree and the large- N approaches resides in the above-mentioned different sensitivity on a finite cut-off, rather than the widely publicized issues related to Goldstone's theorem. In fact, the different properties Hartree and large- N have in relation to Goldstone's theorem are all encoded in the cut-off-dependent contributions to Eq. (16).

⁵It is worth bringing to the attention of those readers who are unfamiliar with the related literature the fact that renormalizability in a non-perturbative approach to a thermal field theory is rather non-trivial. The theorems/proofs we usually advocate to discuss renormalizability are inherently perturbative, and bare no implications for non-perturbative approaches. Moreover, when dealing with a thermal field theory one can encounter (and they have been encountered in this note) ultraviolet-divergent contributions that depend on the temperature, and it is non-trivial to find that there is a temperature-independent (as required by consistency [15, 24, 27]) renormalization scheme, such as (12).

It is tempting to read into (15), and particularly its property (16), also something about the different behavior with temperature of the Hartree and the large- N approaches. As mentioned in the opening of this note, the bubble diagrams are dominant, providing a justification for the Hartree approach, only at high temperatures. However, if N is indeed large, then the (large- N -type) bubble diagrams are the dominant ones independently of the temperature. One would therefore expect the reliability of the large- N approach to be rather insensitive on the temperature, whereas the Hartree approach should get better as the temperature increases. While the computations presented in the present note do not go far enough (and this author's insight is not deep enough) to confirm these expectations, it is worth observing that the deviation from Goldstone's theorem encoded in Eq. (16) becomes less substantial as the temperature increases (in particular, ϕ^2 and $P_f[M_\sigma] - P_f[M_\pi]$ decrease as the temperature increases). In any case, the renormalized Hartree bubble-resummed thermal effective potential derived in the present note for arbitrary N should be useful in future investigations of the $O(N)$ L σ M only when the temperatures of interest (*e.g.*, in setting up studies of type [5, 6]) are not too close to the critical temperature; in fact, neither Hartree nor large- N can be trusted for temperatures very close to the critical temperature, where any type of resummation of bubble diagrams becomes insufficient [25] (*e.g.*, if these inaccuracies are not taken into account it would appear that Hartree predicts a first order phase transition for some theories known to undergo a second order phase transition). The choice concerning whether to use the full Hartree bubble-resummed potential or simply its large- N truncation depends very much on the problem to be investigated, particularly the relevant value of N and the role played by the Goldstone modes. However, the result reported in the present note can be useful also in those instances in which the large- N is preferred, since it provides a rough estimate of the effects being neglected by the leading order in $1/N$. This is particularly important in light of the fact that in most cases one is unable to estimate subleading orders in $1/N$, and the intuition developed in the conventional small-coupling perturbative approaches cannot be trusted to apply to the $1/N$ expansion.
